

Assignment 4

August 12, 2019

You are currently looking at **version 1.1** of this notebook. To download notebooks and datafiles, as well as get help on Jupyter notebooks in the Coursera platform, visit the [Jupyter Notebook FAQ](#) course resource.

```
In [256]: import pandas as pd
import numpy as np
from scipy.stats import ttest_ind
```

1 Assignment 4 - Hypothesis Testing

This assignment requires more individual learning than previous assignments - you are encouraged to check out the [pandas documentation](#) to find functions or methods you might not have used yet, or ask questions on [Stack Overflow](#) and tag them as pandas and python related. And of course, the discussion forums are open for interaction with your peers and the course staff.

Definitions: * A *quarter* is a specific three month period, Q1 is January through March, Q2 is April through June, Q3 is July through September, Q4 is October through December. * A *recession* is defined as starting with two consecutive quarters of GDP decline, and ending with two consecutive quarters of GDP growth. * A *recession bottom* is the quarter within a recession which had the lowest GDP. * A *university town* is a city which has a high percentage of university students compared to the total population of the city.

Hypothesis: University towns have their mean housing prices less effected by recessions. Run a t-test to compare the ratio of the mean price of houses in university towns the quarter before the recession starts compared to the recession bottom. (price_ratio=quarter_before_recession/recession_bottom)

The following data files are available for this assignment: * From the [Zillow research data site](#) there is housing data for the United States. In particular the datafile for [all homes at a city level](#), City_Zhvi_AllHomes.csv, has median home sale prices at a fine grained level. * From the Wikipedia page on college towns is a list of [university towns in the United States](#) which has been copy and pasted into the file university_towns.txt. * From Bureau of Economic Analysis, US Department of Commerce, the [GDP over time](#) of the United States in current dollars (use the chained value in 2009 dollars), in quarterly intervals, in the file gdp1ev.xls. For this assignment, only look at GDP data from the first quarter of 2000 onward.

Each function in this assignment below is worth 10%, with the exception of run_ttest(), which is worth 50%.

```

In [269]: `def run_ttest():`

'''First creates new data showing the decline or growth of housing prices between the recession start and the recession bottom. Then runs a ttest comparing the university town values to the non-university towns values, return whether the alternative hypothesis (that the two groups are the same) is true or not as well as the p-value of the confidence.

Return the tuple (different, p, better) where different=True if the t-test is True at a $p < 0.01$ (we reject the null hypothesis), or different=False if otherwise (we cannot reject the null hypothesis). The variable p should be equal to the exact p value returned from `scipy.stats.ttest_ind()`. The value for better should be either "university town" or "non-university town" depending on which has a lower mean price ratio (which is equivalent to a reduced market loss).'''
